

Simple KPI Tracking Sheet

A KPI Summary Built from Raw Order Data using Excel

Name	Akshat Srivastava
Company	Veda Technology
Role	Intern – Data Analytics
Task	Task 10 – Simple KPI Tracking Sheet
Dataset	Sample Superstore Dataset (100 records, 9 columns)
Tools Used	Microsoft Excel

1. Description

This task involved building a one-page KPI summary — Total Revenue, Total Units Sold, Total Orders, Average Order Value, and Top Product — that recalculates automatically whenever new rows are added to the raw order data.

2. Objective

To practice translating raw transactional data into a small set of business-ready KPIs, using formulas (SUMIFS, COUNTA, INDEX/MATCH) instead of manual totals, so the summary stays accurate as the underlying data grows.

3. KPI Summary Table

The table below shows the five KPIs calculated from the 100-row raw order dataset, along with the formula used for each. Raw data was first converted into an Excel Table (SalesTable) so every formula recalculates automatically when new orders are added.

KPI	Value	Formula Used
Total Revenue	₹17,39,354.61	=SUM(SalesTable[Sales])
Total Units Sold	427	=SUM(SalesTable[Quantity])
Total Orders	100	=COUNTA(SalesTable[Order ID])
Average Order Value	₹17,393.55	=Total Revenue / Total Orders
Top Product	Office Chair	=INDEX/MATCH on SUMIFS by product

4. Category-wise Breakdown

To understand what was actually driving the Total Revenue figure, the raw data was grouped by Category using SUMIFS. The resulting breakdown is shown below.

Category	Orders	Revenue (₹)	% of Total Revenue
Furniture	30	9,97,120.48	57.3%
Technology	41	7,06,912.11	40.6%

Office Supplies	29	35,322.02	2.0%
-----------------	----	-----------	------

5. Write-up: What the Numbers Reveal

At first glance, the KPI summary shows a healthy Total Revenue of ₹17,39,354.61 from just 100 orders, giving a high Average Order Value of ₹17,393.55. But this average on its own hides an important pattern in the data.

- Furniture accounts for only 30% of orders (30 out of 100), but contributes 57.3% of total revenue — because each furniture item (sofas, beds, cabinets) carries a high unit price even in small quantities.
- Office Supplies makes up almost as many orders (29%) as Furniture, but contributes only 2.0% of revenue — these are high-frequency, low-value items.
- Technology sits in between: 41% of orders and 40.6% of revenue — a much closer match between order share and revenue share than the other two categories.

This explains why the Top Product turned out to be Office Chair rather than a frequently-ordered item like Sticky Notes or Printer Paper: Top Product was calculated on total Sales value (SUMIFS), not on order count or quantity, so a category with a high per-unit price naturally rises to the top even without the most transactions.

My Takeaway: A single blended average (like Average Order Value) can look healthy while masking very different behaviour underneath. Before concluding that a KPI reflects the whole business evenly, it is worth breaking it down by a category — here, Category — to check whether a small group of high-value orders is doing most of the work. In this dataset, Furniture turned out to be exactly that hidden driver behind the headline revenue number.
